1.Introduction

[QuollEyeTree](#) is an Xtree like file manager with a GUI interface for Mac OS X v10.6 Snow Leopard or later.

QuollEyeTree is not a complete replacement for Finder but provides additional capabilities and simplifies many tasks. QuollEyeTree facilitates crossing to Finder when required. (For a brief introduction to QuollEyeTree capabilities and design philosophy see ReadMe.txt)

2.Main Window

The initial QuollEyeTree Application Window is divided into 3 principal parts.

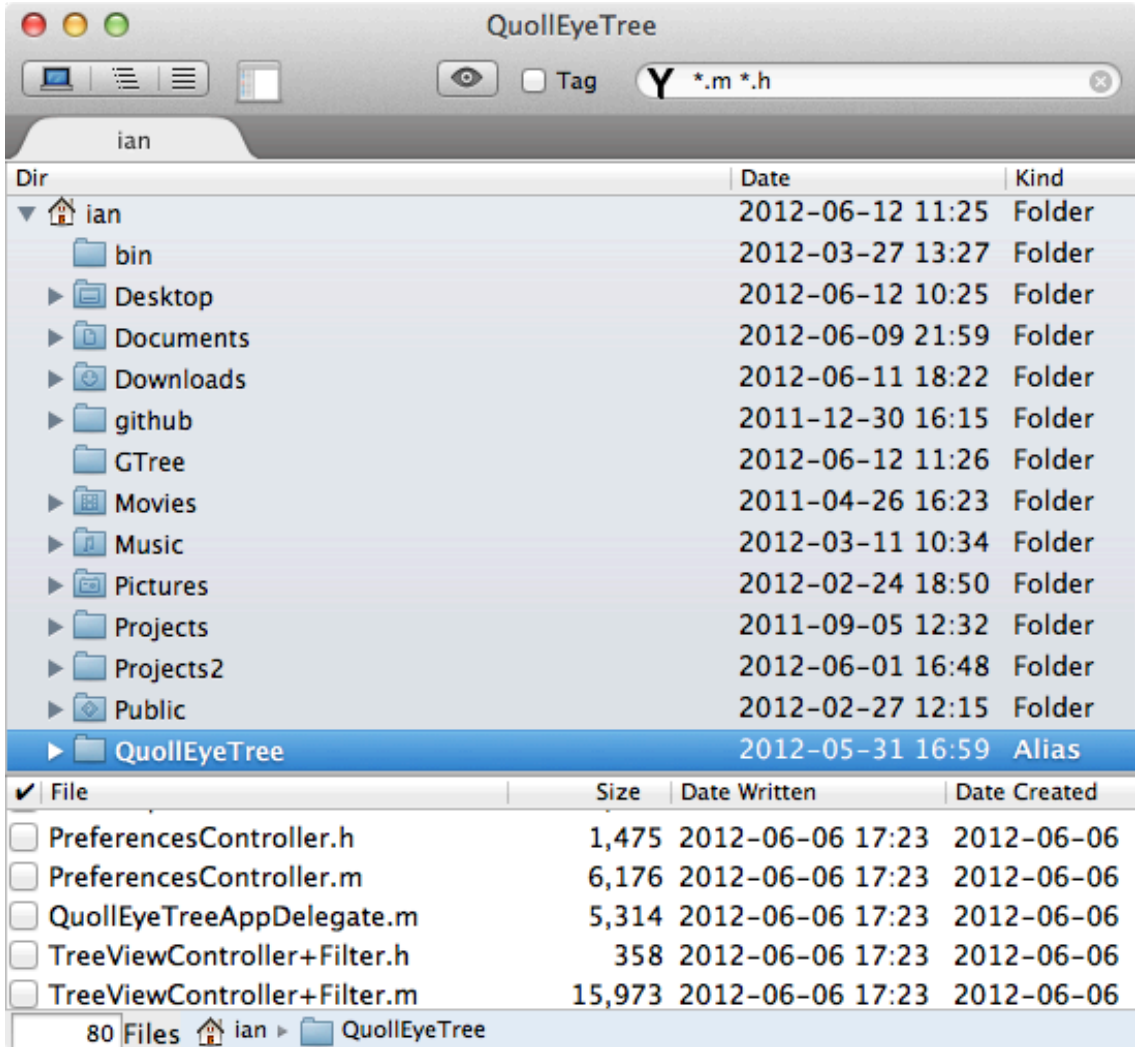

The Tab Bar selects a view containing a Directory Window and a File Window.

The top Directory Window is a tree display of Directories.

The bottom [File Window](#) is a list of Files in the currently selected Directory. The relative sizes of the Directory and File views can be controlled by dragging on the divider.

There is also a Toolbar and a Status box, which contains the path of the current directory.

A [Sidebar](#), similar to the Finder Sidebar, can be opened in a Drawer to the side of the Application Window.

3.Tab Bar

QuollEyeTree has a multi-tabbed interface. Each tab selects a view of the logged file system. The tabs are independent, and maintain their Tree/File/Branch view, [File Filter](#) and tagged only display, but share underlying data including File Filter history etc. Files tagged in one tab will be tagged in other tabs.

Tabs are created or destroyed in the View Menu or the keys:-

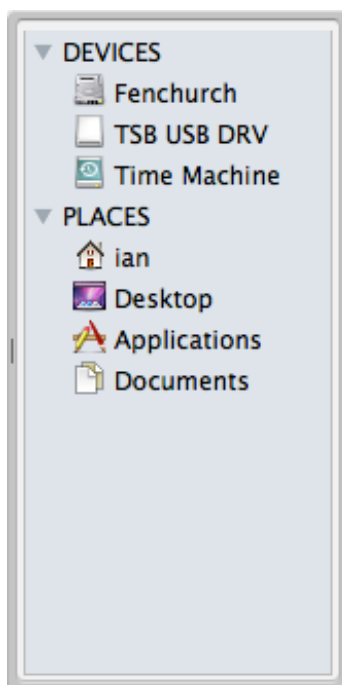

- ⌘T **New Tab** at the default Startup Directory
- ⇧⌘T **New Tab At** the currently Selected Directory
- ⌘W **Close Tab**

Each new tab opens the default Startup Directory or the currently Selected Directory.

Tabs can also be created from the Directory Contextual Commands or [Sidebar](#).

Tabs can be dragged to any position on the Tab Bar.

4.Sidebar

The Sidebar is initially hidden but can be shown from the View Menu, with the  button on the Toolbar or with the Option Command S (⌘S) keys .

The Sidebar shows a list of mounted **Devices**, which is automatically updated and a list of **Places**.

The Places is initialised to a default set, but you can add, delete or re-arrange the Places, which will be saved as the new default.

Clicking on a Device or Place will open the target in the current Tab.

You can add folders to the Places section by selecting **Add to Sidebar** in the Directory Contextual menu.

Control-Clicking on a Device or Place will open a Contextual menu with options to **Open**, **Open in New Tab**, **Eject** and **Remove from Sidebar**.

5.Directory Window

The Directory Window is a tree display of Directories. This is similar to the main Finder display, except that it will never contain files.

The top item displays a single directory, which is the User's home directory by default, although any directory can be selected.

Subdirectories are indented to the right.

The tree may contain a disclosure triangle ▶ indicating that the directory may be expanded or ▼ indicating that it is already expanded.

While in the Directory Window, the Status Box shows the path to the selected directory, and the count of files in that directory.

5.1.Directory Window Navigation

The Directory Window can be navigated with the mouse or trackpad, by clicking on a directory, the Go Menu or the View selector in the Toolbar

Show the root directory “/”

Make the selected directory the top directory.

Show the Maximised File Window.

or by using the following keys and clicks:-

Up/Down Arrows

Move a single row, scrolling if necessary.

Click ▶

Expand first-level subdirectories of the selected directory

Right Arrow (→)

+

Option-click ▶

Expand all subdirectories within the selected directory

Option-Right Arrow (⌘→)²

*

Option-click ▼

Collapse the selected directory.

Option-Left Arrow (⌘←)

-

Command-Up Arrow (⌘↑)

Show the directory Enclosing the top directory.

Double-click

Make the selected directory the top directory.

F5

Toggle between collapsing/expanding the second-level subdirectories of the selected directory.

F6

Toggle between collapsing/expanding the first-level subdirectories of the selected directory.

5.1.1.Path Bar

Double-clicking any of the directories in the Path Bar navigates to that directory.

5.1.2.Go Menu

The **Go Menu** provides a quick way to navigate to common Directories and the **Go To** menu item  ⌘G allows entry of paths e.g. ~/Pictures.

The **Go To Menu** is similar to the Finder Go To Folder menu. The **Tab** key will complete partially typed entries and the **F5** key will display a list of possible values if there are a number of possibilities.

NOTE QuollEyeTree will enable access to hidden files in the enclosing directories if necessary to log the entered path.

5.2.Directory Window Logging

Directories need to be logged before they can be used. QuollEyeTree saves directory contents in an internal database.

QuollEyeTree does not have any specific commands for logging. All first level subdirectories and files are logged on startup or on creation of a new tab, and the contents of subdirectories are logged as they are selected or displayed. (see [Directory Window Navigation](#))

This is similar to Finder, but there are 2 important differences. Once logged the contents are kept in memory, but they are not automatically refreshed if the contents change. There is a command to refresh directory contents, and optional [Automatic Refresh](#).

When QuollEyeTree 'logs' a directory it loads the path back to the root. Although only the logged directory is initially displayed, all directories back to '/' are loaded into memory. It is possible to select any directory as the apparent root of the display.

Symbolic links (and Aliases) are loaded into the appropriate position in the FileSystem (and the path back to '/' is loaded into memory). No matter how many links point to a target it will only be loaded once.

By default, QuollEyeTree does not log hidden files or directories. The default may be changed (see [Configuring QuollEyeTree](#)).

5.3. Automatic Refresh

QuollEyeTree can optionally refresh the logged directories to reflect external changes. This is done by periodically monitoring a specified directory in the file system for changes.

There is also an option to specify the directory which is monitored. This is initially set to the User Home Directory (see [Configuring QuollEyeTree](#)).

It is preferable to set this to either the default Startup Directory or User Home Directory. It is inadvisable to set this to the root '/' as the number of changes could swamp the program.

5.4. Directory Window Commands

Enter Enter the [File Window](#). This is only possible if there are visible files in the directory.

F3 Refresh the Directory contents

B Enter the [Branch Window](#).

S **Show All** files on the volume.

T **Tag All Files** in the File Window.

U **Un-Tag all Files** in the File Window.

⌘C **Copy** Directory to the clipboard

⌘V **Paste** from clipboard into Directory

C **Copy Dir To** see [Copy Move Menu](#)

M **Move Dir To** see [Copy Move Menu](#)

R **Rename Dir**

⇧⌘N **New Dir**

O **Open Directory** in Finder.

⌘R **Reveal in Finder**

⌘I **Get Info**

⌘C **Compare Dir** see [Compare Directories](#)

⌘. **Toggle [Hidden](#)**

⇧⌘. **Toggle All [Hidden](#)**

⌘⌘ **Move Directory to [Trash](#)**

Put Back Menu see [Move to Trash](#)

^Enter Toggle File Window display between tagged files or all files.

^B Enter the [Branch Window](#), showing only Tagged.

^S **Show All** Tagged files on the volume.

^⌘C **Copy tagged** Files to the clipboard

5.5.Directory Contextual Commands

Control-click (Secondary-click Right-click)	Show the Directory Contextual menu.
Open Dir	Open the Directory in Finder.
Reveal in Finder	Open Finder with the Directory selected.
Get Info	Display the Finder Info Window for the Directory selected
Copy Path	Copy Directory path to the clipboard.
Copy Dir	Copy Directory to the clipboard (it can be pasted in Finder)
Open in Terminal	Open a Terminal window at the directory.
Open in New Tab	Open a New Tab with the Directory as root.
Make Root	Make Directory the root of the current Tab
Add to Sidebar	Add the Directory to Places in the Sidebar

6.File Window

The File Window displays a list of files and information. Initially there is a Small File Window below the Directory Window, but it can be maximised to fill the Window.

The Normal File Window displays all files in a directory which match the current File Filter.

The Status Box shows the path to the current directory, and the count of files which match the current File Filter.

The left column contains a checkbox; ☒ indicates that the file has been “tagged”.

You can view the contents of files with the [Quick Look](#) feature.

6.1.File Window Navigation

The File Window can be navigated with the mouse or trackpad, by clicking on a directory, the View selector in the Toolbar

Toggle between the Maximised and Small File Window.

or by using the following keys:-

Up/DownArrows Move a single row, scrolling if necessary.

Double-click Open the File in the default application.

6.2.File Window Commands

Enter	Enter the Maximised File Window. If already Maximised return to the Directory Window .
Esc	Return to the Directory Window .
T	Tag the selected file and select next.
U	Un-Tag the selected file and select next.
O	Open File in the default application.
⌘R	Reveal in Finder

⌘I	Get Info
C	Copy File To see Copy Move Menu
M	Move File To see Copy Move Menu
R	Rename File
⌘C	Copy File to the clipboard
⌘⌘	Move File to Trash
	Put Back Menu see Move to Trash
⌘Y	Open Quick Look
V	View file in internal File Viewer

6.3.Control (^) File Commands

^T	Tag All files in the File Window.
^U	unTag All files in the File Window.
^I	Invert Tags in the File Window.
^⌘C	Copy tagged Files to the clipboard
^C	Copy tagged Files To see Copy Move Menu
^M	Move tagged Files To see Copy Move Menu
^R	Rename tagged Files To
^⌘⌘	Move Tagged Files to Trash
^Enter	Toggle File Window display between tagged files or all files.
^S	Search tagged files (see Searching Content)
^V	View tagged files in internal File Viewer

6.4.File Contextual Commands

Open File	Open the File in the default application.
Open With	Display a menu of application which can open the File.
Reveal in Finder	Open Finder with the File selected
Get Info	Display the Finder Info Window for the File selected
Show Package Contents	Show Package in Directory Window
Copy Path	Copy File Path to the clipboard.
Copy File	Copy File to the clipboard (it can be pasted in Finder)
Copy tagged Files	Copy all tagged Files to the clipboard.

6.5.File Tagging

There are many ways of tagging files, with the mouse or keyboard (see [File Window Commands](#) and [Control \(^\) File Commands](#)) or with the [Compare Directories](#) Command. The group tagging operations only affect files which are currently available for display in the [File Window](#), even if they are scrolled off the visible screen. This effectively means files which satisfy the current [File Filter](#).

It is possible to display only tagged files in the [File Window](#) or [Branch Window](#) using the ^ **Enter** keys or clicking the ☒ button near the File Filter on the Menu bar.

6.6.Expanding Compressed (Archive) Files

Double clicking (or Opening) a compressed file will invoke the default application, which is usually Archive Utility.app. This will extract the contents into a directory with the same name as the compressed file.

Archive Utility.app is not documented by Apple, but appears to handle file types (.bz, .bz2, .cbz, .cpgz, .cpio, .gzip, .gz, .tar, .tgz, .tbz, .tbz2, .jar, .z, .zip) as a front end to the inbuilt BSD utilities.

One unfortunate side affect of Archive Utility.app is that after extraction it activates Finder. You can change this (and other Archive Utility preferences) by the following:-

Navigate to /System/Library/CoreServices and click on the Archive Utility.app (alternatively enter `open -a /System/Library/CoreServices/Archive\ Utility.app` in Terminal).

- In the Archive Utility.app Preferences Menu (⌘,) Un-check "Reveal expanded item(s) in Finder"

7.File Filter

File Filters are a means of controlling which files are displayed in QuollEyeTree and work hand in hand with Tagging to select a subset of files for subsequent operations.

Only files which match the current File Filter are displayed in the File Window.

File Filters are entered in the Filter Field to the right of the toolbar, which can be activated by clicking in the field or from the keyboard with 'F'.

Filters have no effect until the entry is complete, either by pressing Return or clicking on the filter button **Y**.

Filters can be made up from up to 3 components **Name Filter**, **Size Filter** and **Date Filter**.

7.1.Name Filter

The Name Filter comprises one or more patterns separated by spaces.

Each pattern may contain '*' and '?' wildcards: '*' matches an arbitrary, possibly empty, string, '?' matches an arbitrary character.

Patterns preceded by '!' will include only files which do not match the pattern.

Example *.txt *.doc !report*. * would show all txt and doc files, except those which start with report.

7.2.Size Filter

The Size Filter is indicated by a leading pattern **=s >s <s >=s <=s <>s** followed by a number (**!<s !>s =>s =<s !=s** are also accepted) to select files based on size.

Adjacent patterns which overlap are recognised e.g. >500 <1000 will select only files with sizes greater than 500 **and** less than 1000

7.3.Date Filter

The Date Filter is indicated by a leading pattern **= > < >= <= <>** followed by a date (**!< !> => =< !=** are also accepted) to select files based on date.

Adjacent patterns which overlap are recognised.

Dates should be entered in a format which matches the configured Date Format, but QuollEyeTree will attempt to match against ISO 8601 and Short/Medium and Long locale dependent variants. OS X is rather inflexible in interpreting Long dates so the use of Short/Medium formats is recommended. ISO 8601 format yyyy-mm-dd can be used in any locale.

QuollEyeTree also allows TODAY and TODAY±n as valid dates.

7.4.Compound Filters

Filters can have 1, 2 or 3 of the components Name Filter, Size Filter and Date Filter and each component can have multiple elements.

Elements must be separated by spaces and may occur in any order and may optionally be enclosed in quotes.

***.doc <s10000 >=2012-05-01 <=2012-05-31** would show all .doc files smaller than 10,000 which were saved in May 2012.

Technical Note

Name Filter patterns are combined with OR logic except ! patterns which use AND NOT.

Size and Date Filter elements are combined with OR logic except adjacent overlapping elements which use AND.

The resultant Name Filter, Size Filter and Date Filter are combined with AND logic.

7.5.Filter History

File Filters are remembered in a history list. Previous values can be selected from a pull-down list shown by clicking on the filter button **Y**.

As new filters are entered the oldest values will be removed. The pull-down list has a menu which allows filters to be marked to ensure they are not forgotten. Marked filters are shown with a '◇' symbol.

8.Searching

QuollEyeTree has powerful search capabilities, even though it does not have an explicit Search.

8.1.Searching for Files

To find files by **name**, **size** or **date** enter a [File Filter](#). This will show files which match in the File Window.

In Normal mode this will show files in the current Directory.

In Branch mode all logged files in the Branch and

in Show All mode all logged files on the volume.

E.g. to find all matching files in your home directory, select Home, log all with '*' then enter Branch mode with 'B'.

8.2.Searching for Content

To find files with **specific content**, first tag the files of interest (possibly using a [File Filter](#) to limit the search) then search with ^S. If the string is not found, then the file is untagged, so that all remaining tagged files contain the string.

The **Search tagged Files** (^S) command brings up the Search Files Menu where you can enter the **search pattern**, whether the search is **Case Sensitive** and the type of search.

- **String**
- **Basic regex**
- **Extended regex**
- **Perl regex**

There are 2 buttons **Cancel** and **Search** to initiate the Search.

The actual search is performed by the UNIX grep utility. Type 'man grep' for documentation.

The **String** search will find any simple literal string (uses grep -F).

The **regex** options perform more advanced searches see [Regular Expressions](#)

9.Quick Look

Using the Quick Look feature, you can quickly view the contents of a file without opening it or starting an application.

Click the Quick Look button  , or the ⌘Y keys.

A Quick Look window opens with the selected file displayed. To enlarge the window, drag the lower-right corner or click the double arrows to switch to full screen view.

Continue previewing files by selecting files in the [File Window](#). The Quick Look window displays each file as you select it.

To close the preview, click the Quick Look button (or press the the ⌘Y keys) again, or click the close (x) button in the Quick Look window.

The content you see depends on the type of item you're previewing. If it's an image, you see a smaller version of it. If it's a text document, you can read the text and scroll to see more.

10.File Viewer

QuollEyeTree has a built in viewer for Text Files which is invoked from the [File Window](#) with the V or ^V command.

You can find text within the file. The F command brings up the Search Files Menu which is populated with the last search (see [Searching Content](#)). In Snow Leopard only **String** searches are possible; in Lion [Regular Expression](#) searching is possible, but all RegEx use ICU's Regular Expressions regardless of RegEx options.

All occurrences found are marked, and the first is highlighted. You can move between found occurrences with '+' and '-'.

If multiple files are selected with the ^V command you can move between files with 'N' and 'P'.

10.1.File Viewer Commands

Esc	Return to the File Window
F	Find all occurrences of text in the File
+	Select Next occurrence of text
-	Select Previous occurrence of text
>	Select occurrence on Next page
<	Select occurrence on Previous page
N	View Next tagged file
P	View Previous tagged file

NOTE: If the TextEncoding is stored in the file's extended attributes this will be used to convert the file. Otherwise QuollEyeTree will test to see if the file is Unicode, or Windows CP1252. Failing this the file will be displayed as ISO-8859-1 characters with control characters replaced by a Square □.

The viewer is intended for examining text files, but can be used to look for text in any file. Only the first 500k of the file will be displayed.

11.Regular Expressions

Regular Expressions (RegEx) are quite powerful, but can be complex - whole books have been written about them. The situation is complicated by differences in syntax (and capabilities) between different implementations.

The following is a simple introduction to the basic RegEx syntax common to all implementations:-

Alphanumeric characters match themselves.

. (dot) matches any character except line break

[abc] match any of the characters a, b or c

[^abc] match any character except a, b or c

[A-X] match any character from A to X

^ match start of line (only valid as 1st character)

\$ match end of line (only valid as last character)

\ escapes one metacharacter e.g. \. will match the Full Stop character

Much of the power comes from the quantifiers:-

? The preceding item is optional and matched at most once

* The preceding item will be matched zero or more times

+ The preceding item will be matched one or more times

Basic needs to use \?, \+ as ? and + are treated as normal characters.

Beware '*' matches as much as it can, which may be more than you expect!

[A-Z][a-z]* will match any word which begins with a capital.

Basic regex has the same capabilities as **Extended regex**, but is more verbose and is best for simple searches. Type 'man grep' in a terminal for documentation, in particular the pattern.

Perl regex is more powerful. See:-

<http://perldoc.perl.org/perlre.html> Syntax of regular expressions in Perl

ICU's Regular Expressions are included in Lion, and used for RegEx searches in the File Viewer. The syntax is similar to **Perl regex**.

<http://userguide.icu-project.org/strings/regexp>

12.Branch Window

Branch mode displays all files in the selected directory and in all logged directories under the selected directory. The files are displayed in a single list in the [File Window](#).

Show All mode displays all logged files in the volume, but otherwise is the same as Branch mode.

Once displayed, Branch mode operates the same as File mode. The Status Box shows the path to the directory containing the selected file, and the count of files in the Branch which match the current File Filter.

The background colour of the [File Window](#) is changed to indicate Branch mode is in operation. The colour will be light blue for the default Aqua scheme.

Branch mode is cancelled when you return to the [Directory Window](#).

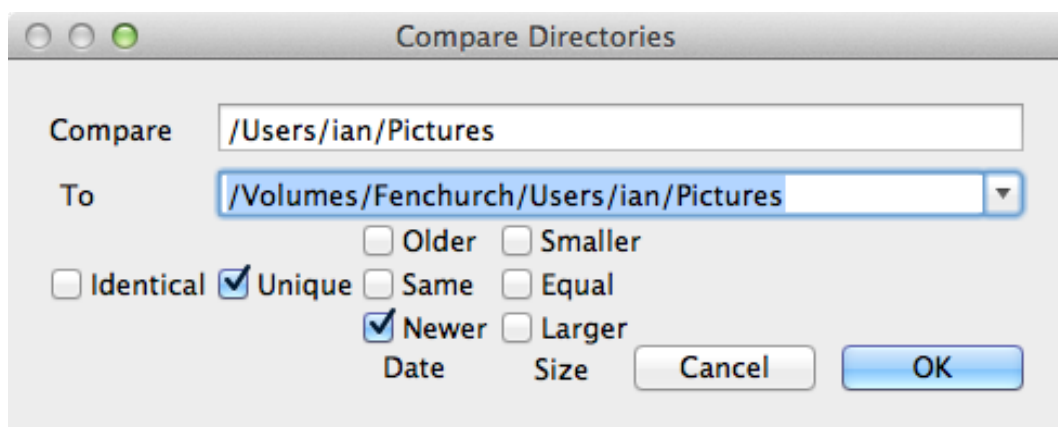

Branch mode follows logged links (Aliases or symbolic links) and skips links which point within the branch to avoid duplicate entries.

NOTES Branch mode displays logged directories; if a directory has never been displayed on screen it may not be logged e.g. directories at the bottom which are off screen.

Similarly there may be directories included which have been logged because they are the target of logged links, and of course, any intermediate directories in the path.

13.Compare Directories

Compare matching files in the current directory with those in a target directory, and tag the files in the current directory that match the options chosen.

- The 1st line (**From**) shows the current Directory (for information).
- The 2nd line (**To**) is the target Directory. This is a pull down list which is populated with the currently selected directory in each Tab. For convenience the Tab to the right is selected (or the left if there is no right Tab). You can select any of these, edit the contents, or enter a new destination Directory.
- **Identical** Files that are identical in both size and date (timestamp).
- **Unique** Files that do not have a file with the same name in the target directory.
- **Older** Files that have an older date (timestamp) in the current directory.
- **Same** Files that have the same date (timestamp) in the current directory.
- **Newer** Files that have a newer date (timestamp) in the current directory.
- **Smaller** Files that are smaller in the current directory.
- **Equal** Files that are the same size in the current directory.
- **Larger** Files that are larger in the current directory.
- There are 2 buttons **Cancel** and **OK** to initiate the Comparison.

Combinations of the options can be used e.g. you can tag files that are Unique "or" Newer to find files which have been added or changed.

13.1.Compare Limitations

The target Directory must already exist, and be logged.

Note that OS X timestamps are accurate to fractions of a second, but fractions are not used when performing the comparison.

14.Copy & Move

QuollEyeTree has 2 approaches to copying Files and Directories.

14.1.Clipboard

Copy (⌘C) Copies the selected File or Directory to the Clipboard.

Copy tagged Files will copy all tagged Files to the clipboard.

There are corresponding Contextual Menu Commands **Copy File**, **Copy Dir** and **Copy tagged Files**.

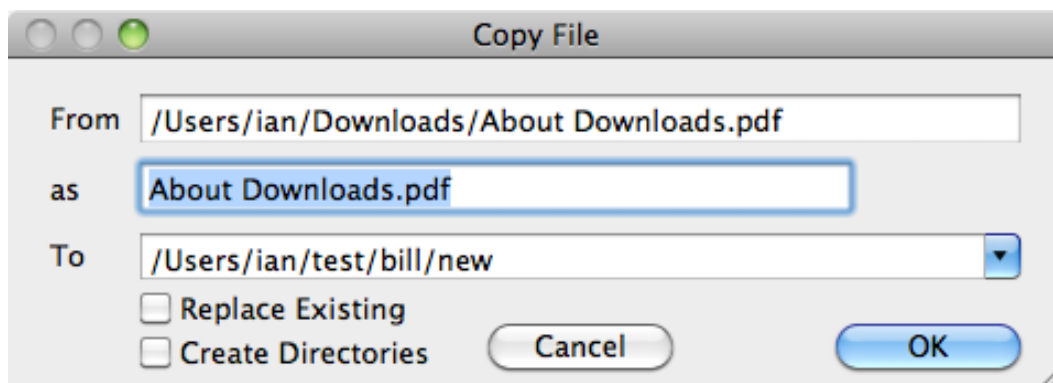

The Clipboard contents can be pasted into the selected Directory with the **Paste (⌘V)** command.

The results of **Paste** are similar to **Copy File To**.

Clipboard contents can be exchanged with Finder and other applications which support the protocol.

14.2.Copy/Move Menu

The **Copy File To (C)**, **Copy tagged Files To (^C)**, **Move File To (M)** and **Move tagged Files To (^M)** commands bring up the Copy/Move Menu.

- The 1st line (**From**) shows the source path (for information) or a indication of the number of tagged files to be copied/moved.
- The 2nd line (**as**) is the name. This will be used as the name of the File or Directory and can be edited or replaced with a [Rename Mask](#). The mask is initialised to “*. *” if tagged files are to be copied/moved.
- The 3rd line (**To**) is the destination Directory where the File or Directory to be copied or moved will be placed. This is a pull down list which is populated with the currently selected directory in each Tab. For convenience the Tab to the right is selected (or the left if there is no right Tab). You can select any of these, edit the contents, or enter a new destination Directory.
- **Replace Existing** will cause any existing File or Directory to be deleted, without prompt.
- **Create Directories** will create new Directories if the destination Directory does not already exist.
- There are 2 buttons **Cancel** and **OK** to initiate the Copy or Move.

The destination path is created by combining the destination Directory with the renamed file or directory.

If source path is a file, **Copy File To** creates a file in the destination Directory with identical contents to the original file.

If source path is a directory, the **Copy File To** creates a new directory in the destination Directory and recursively populates it with duplicates of the files and directories contained in source, preserving all links.

Symbolic links are not traversed but are themselves copied. File or directory attributes—that is, metadata such as owner and group numbers, file permissions, and modification date—are also copied.

Move File To moves the directory or file specified by source path to the destination Directory. If the source path and the destination path are not on the same device, **Move File To** performs a copy to the destination path and removes the original. If the copy does not succeed, it removes the incomplete copy, leaving the original in place.

14.3.Copy/Move Limitations

The destination path must not exist, and an Alert will display if it exists. This offers an option to replace the existing File or Directory. If Replace is selected the existing File or Directory will be deleted (similarly to Finder). If in doubt you may wish to Cancel, and manually move the existing File or Directory to Trash.

The destination Directory must already exist, and an Alert will display if not. This offers an option create new Directories.

You can Copy, but not Move Locked files. If you need to move a locked file, first copy, then [Move to Trash](#).

14.4.Copy/Move/Paste Progress Indication

Copy, Move and Paste will display a Progress Bar for the duration of the operation. You can continue to perform other tasks, including switching to other tabs during this.

QuollEyeTree may display Alerts (prompting to Replace Existing or Create Directories) early in the process and any Error Alerts.

The destination Directory will not normally be updated until all operations are complete, although you can manually Refresh the Directory contents with F3. [Automatic Refresh](#) is also suspended for the duration.

14.5.Move to Trash

Files and Directories can be Moved to Trash from various Menus or with the keyboard shortcuts ⌘⌘ or ^⌘⌘.

QuollEyeTree keeps track of the last 25 Files or Directories moved to Trash and provides a mechanism to restore these to their original location from the **Put Back Menu** (just after Move to Trash in the File and Dir Menus). This Menu shows a list of the original names and the time and date they were removed.

NOTE only items Moved to Trash in QuollEyeTree are shown (not those Moved to Trash in Finder). Similarly these those Moved to Trash in QuollEyeTree (or any other program) are not shown in the Finder Put Back Menu.

If you attempt to move a group of tagged files to Trash any Locked files will not be moved and QuollEyeTree will display an Error Alert. Locked files can be unlocked (in Finder) or deleted one at a time; QuollEyeTree will prompt for each file.

15.Rename Mask

Rename mask allows you to change the name of the File or Directory to be copied.

The Mask mask may contain any characters which are acceptable in a File Name and wildcard characters '*' and '?'. Any normal characters are copied, '?' is replaced by the character in the corresponding position in the original name, '*' is replaced by the remaining characters in the original name and is equivalent to a string of '?'. Only a single '*' may be used in name and extension.

The following examples serve to explain how to use masks.

In all examples the original name is "abcdef.xyz"

Mask	Target
.	abcdef.xyz
*.bak	abcdef.bak
A*.*	Abcdef.xyz
A*M.*	AbcdefM.xyz
A?M.*	AbM.xyz
ABC.XYZ	ABC.XYZ
ABC.	ABC
ABC	ABC
ABC.DEF.*	ABC.DEF.xyz
.ABC.*	.ABC.xyz

16.Package Contents

Apple has added a number of features to the underlying UNIX file system.

Packages (also known as Bundles) are actually directories, but the contents are hidden and they usually appear to be a file. The most common is the .app application.

Finder allows you to "Show Package Contents", QuollEyeTree also has a "Show Package Contents" option in the File Contextual Menu which treats the Package as a directory.

Packages do not have a file size. Finder appears to calculate the size by adding the sizes of its contents (this can be seen in action by opening Applications). QuollEyeTree does not display a size for Packages.

17.Hidden Files and Directories

The UNIX filesystem hides files which commence with the '.' character and OS X has an additional hidden attribute. (Very few directories actually have a hidden attribute ~/Library in Lion, and handful under the root '/')

QuollEyeTree does not log hidden files or directories but this may be changed (see [Configuring QuollEyeTree](#)). The very large number of hidden files (most of which are of no interest) makes their display distracting, so QuollEyeTree can toggle display of hidden files and directories in individual directories.

⌘. will toggle display of items with a hidden attribute in a directory.

⇧⌘. will toggle display of all hidden items in a directory.

To display ~/Library toggle the hidden status of the users home directory ~

The [Go Menu](#) provides a quick way to navigate to ~/Library and the **Go To** menu allows entry of paths to hidden directories. QuollEyeTree will enable appropriate access in the enclosing directory.

18. Configuring QuollEyeTree

QuollEyeTree default settings can be changed through the Preferences Menu (⌘,).

Most changes only take effect the next time QuollEyeTree is started, although default Directory, Column settings and Percentage Split will apply to any newly created Tabs. Date and Time changes apply immediately to all existing and newly created Tabs.

18.1. General

You can set:-

- File Sort Order
- Whether icons will be displayed in Directory or File windows
- Whether hidden Files or Directories will be displayed.
- The default Startup Directory.
- Automatic Refresh.
- Directory to monitor for Automatic Refresh.

The default **Startup Directory** must be in the main Volume - it cannot be in any other mounted Volume.

18.2. Changing the Appearance of QuollEyeTree

You can change the following items which affect appearance:-

- Date and Time display
- Percentage Split of Directory Window (10% - 90%)
- Column Width, Visibility, Order

You can select from a number of options for **Date and Time** display including 2 variants of ISO 8601 and 4 locale dependent variants. The Long and Full options are probably too long for practical use.

QuollEyeTree attempts to calculate the width of the Date Columns but it may be necessary to manually set the width and save new defaults.

You can change the width and position of File and Directory Window **Columns** by dragging headers and hide/un-hide Columns from the header Control-click menu. This is similar to many OS X programs.

- You cannot hide the **Dir** or **File** columns, or move any other column to the left of these columns.
- Changes apply independently to each tab.
- To change the defaults customise the columns in a tab and select Save **Column Width, Visibility, Order** in the Preferences Menu (⌘,)

19. Automator Actions

QuollEyeTree includes an Automator action *OpenInQuollEyeTree* which enables external applications to open a Directory in a new QuollEyeTree tab. In order to use this action, QuollEyeTree must be running.

OpenInQuollEyeTree will be available in the Files & Folders Automator Library after you have installed QuollEyeTree and you can use this to create your own workflow.

You can use the `OpenFolderInQuollEyeTree.workflow` included in the QuollEyeTree download to add *OpenFolderInQuollEyeTree* to the Finder Services menu. Double-click on the file in the installation to install.

20.Documentation & Support

This document can be accessed from the Help Menu.

There is Menu item to generate an email for support. Any feedback or suggestions are welcome.

21.What's in a Name

QuollEyeTree (pronounced to rhyme with Quality) is a Mac OSX File Manager which provides a cat's **Eye** view into the OSX file system which it represents as a **Tree**.

The **Quoll** or native cat (genus *Dasyurus*) is a carnivorous marsupial native to Australia. Quolls are primarily nocturnal and partially arboreal. The name **Quoll** continues the Mac cat metaphor Leopard, Tiger, Snow Leopard.

The icon is a representation of the Australian Ghost Gum.

22.Security and Privacy

QuollEyeTree accesses the OSX file system, but does not access any information about the user. It does not even look at the contents of your files (unless you use the viewer or search). All file system access is through standard system libraries.

QuollEyeTree does not access the Internet or any of your hardware.

If you generate a support email this will be populated with versions of the OS and QuollEyeTree you are using.
